

# Solution 1: Basic programming in R

Yuan Tian

07/10/2023

## Part 1: Matrix and vector operations.

1. Solve the following system:

$$\begin{bmatrix} a_1 & b_1 & & & 0 \\ c_1 & a_2 & b_2 & & \\ & \ddots & \ddots & \ddots & \\ & & & a_{99} & b_{99} \\ 0 & & & c_{99} & a_{100} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_{100} \end{bmatrix} = \begin{bmatrix} d_1 \\ d_2 \\ \vdots \\ d_{100} \end{bmatrix}$$

where

$$a_j = j, \quad b_j = 1/j, \quad c_j = 1, \quad d_j = \sin(j\pi/200)$$

and print  $x_1, x_2, \dots, x_5$ .

**Solution:**

```
# Define A.
A <- matrix(rep(0, 100*100), nrow = 100, ncol = 100, byrow = TRUE)

for (i in c(1:100)) {
  A[i, i] <- i

  if (i + 1 < 101) A[i, i + 1] <- 1/i
  if (i - 1 > 0)   A[i, i - 1] <- 1
}

# Define D.
d <- c(1:100)
d <- sin(d*pi/200)

# Solve Ax = d.
x <- solve(A, d)
x[1:5]
```

```
## [1] 0.005473329 0.010233988 0.010938907 0.012167224 0.012730871
```

## Part 2: For loops.

1. Write a function that uses a `for` loop to calculate the following with a sequence of  $m$ , and generate a plot for  $m$  verses  $E_m$ . Avoid using a `for` loop, can you complete the same task?

$$E_m = 1 + \frac{1}{2} + \cdots + \frac{1}{2^m} - \log(2^m)$$

**Solution:**

```
# Using for loop.
E_m <- function(m) {
  res <- 1
  for (i in c(1:m)) {
    res <- res + 1/(2^i)
  }
  res <- res - log(2^m)

  return(res)
}

# Avoid using for loop.
E_m2 <- function(m) {
  res <- 1

  index <- c(1:m)
  denom <- 2^index
  res <- res + sum(1/denom)

  res <- res - log(2^m)

  return(res)
}

E_m(100)
```

```
## [1] -67.31472
```

```
E_m2(100)
```

```
## [1] -67.31472
```

2. Let's draw a regular polygon of  $n$  sides, with a horizontal bottom side, and the corners of the polygon staying on the unit circle. For given  $n = 5$  and  $r = 0.6$ , start the first point  $p_1 = (x_1, y_1)$  as a random number in  $(-0.5, 0.5) \times (-0.5, 0.5)$ , generate  $10^4$  points interactively. In the  $j$ th iteration, we choose one corner  $z_*$  of the polygon randomly and let  $p_{j+1} = (x_{j+1}, y_{j+1})$  be the point on the line segment between  $p_j$  and  $z_*$ , with the distance from  $p_{j+1}$  to  $p_j$  being  $r$  times the distance from  $z_j$  to  $p_j$  and then draw all these points as dots in the  $xy$  panel.

Hint: Complex numbers can be used to represent points in the  $xy$  plane. The following script works for even or odd  $n$ , and the polygon always has a flat bottom.

```
n <- 5
t <- c(0:n) - 0.5
z <- exp(2i * pi * (t/n - 0.25))
```

```
plot(Re(z), Im(z))
```

**Solution:**

```
n_points <- 10000

# generate 10000 points
p <- rep(NA, n_points)

# starting from the 1st point from [-0.5, 0.5]x[-0.5, 0.5]
rand <- runif(1, min = 0, max = 1)
p[1] <- rand - 0.5 + 1i * (rand - 0.5)

# r x distance of d(z_j, p_j)
r <- 0.6

# set up the n sides polygon and n corners
n <- 5
t <- c(0:n) - 0.5
```

```
z <- exp(2i * pi * (t/n - 0.25))  
  
# in the jth iteration, randomly choose one corner and update p(j+1)  
for (j in c(2:n_points)) {  
  # sample 1 corner  
  zs <- z[sample(n, 1)]  
  p[j] <- p[j-1] + r*(zs - p[j-1])  
}  
  
plot(Re(p), Im(p))
```
